Gender in Teaching: Insights from Five Million Syllabi on Collaboration, Interdisciplinarity, and Reading Selections

Andrea Blasco* Elisa Orlandi†

Abstract

This study examines the formation of academic teaching teams and how their gender composition is associated with course design and gender disparity in academic recognition. Analysing over five million syllabi from higher education in fifteen countries, we document a persistent underrepresentation of mixed-gender co-teaching teams, which occur 50% less frequently than expected under gender-neutral team formation. We link team gender configurations to critical course characteristics: interdisciplinarity, novelty of reading materials, and gender balance in assigned citations. Courses taught by mixed-gender teams are significantly more interdisciplinary than those taught by same-gender teams. Male-only teams cite substantially fewer female authors than female-only teams, and mixed-gender teams do not eliminate this gap. Moreover, courses led by solo female instructors or teams including at least one woman tend to incorporate more recent reading materials, while mixed-gender teams tend to cite more conventional readings and fewer readings at the research frontier. These findings reveal persistent gendered patterns in teaching collaboration and content and point to mixed-gender co-teaching as a potential lever to promote interdisciplinarity and gender equity in academic representation.

JEL Classification: I21, I23, J16

Keywords: education | gender bias | teams | interdisciplinarity | novelty | syllabi

1 Introduction

Universities and other higher education institutions are central to producing and disseminating knowledge, contributing to human capital development. Instructors' choices – how to teach, which materials to assign, and whether to collaborate with colleagues – shape students' educational experience, influencing their learning outcomes and career trajectories substantially (1–3). These choices reflect both individual preferences and institutional constraints, which may not always align with students' learning needs or societal objectives. For instance, instructors may prefer to work alone or collaborate with colleagues with similar backgrounds, which can limit course diversity or interdisciplinarity and reinforce gender stereotypes in specific subjects (4–6). Collaboration can also advance instructors' professional development by exposing them to different pedagogical approaches or teaching methods (7). Yet, despite their significance, the factors shaping these teaching choices remain poorly understood, primarily due to a lack of data.

This study addresses this gap by analysing a large dataset of English-language course syllabi from 1990 to 2019 across fifteen countries and from 2019 to 2023 across thirty-three European countries. These data, which have been previously used in research on school curricula (3), teaching metrics (8), the impacts of AI (9), and the education-innovation gap (10), enable a systematic, quantitative analysis of long-term trends. Each syllabus includes the instructor's gender, institutional affiliation, course field, assigned readings, and a course description. This information allows us to examine gender-based team formation, revealing potential preferences and institutional constraints in teaching collaborations. Furthermore, we analyse how team composition, particularly gender and size, relates to teaching practices, such as interdisciplinarity and reading assignments, while controlling for institutional factors, field, academic year, and other relevant variables.

We investigate three central questions: (i) how gender and institutional constraints are associated with the formation of teaching teams; (ii) whether instructor gender is associated with the inclusion of female-authored readings; and (iii) whether mixed-gender teams are linked to greater interdisciplinarity in course content and with the adoption of novel or unconventional readings, including materials that are recent or at the frontier of research ("scientific novelty"). Previous research shows that these teaching choices shape students' learning outcomes and career trajectories (1–3), and they can also influence instructors' professional development and promotion within their institutions (7).

We complement these analyses with an exploration of the formation of teaching teams in Europe pre- and post-COVID-19. The COVID-19 pandemic disrupted academic work in many countries, especially for women and caregivers (e.g., 11), reshaped collaboration networks, and accelerated the shift to online and hybrid teaching. The shift to online and hybrid teaching may also have affected team formation across gender and disciplines. Using COVID-19 as an exogenous shock, we study changes in the prevalence and gender composition of teaching teams around 2020.

Our results reveal a significant role for gender in co-teaching practices, with mixed-gender teams occurring consistently less frequently than same-gender teams across institutions and fields. Furthermore, mixed-gender teams arise much less often than expected under a null model that forms teams in a gender-neutral manner while holding field-related and institutional constraints fixed. These findings underscore a persistent and widespread underrepresentation of mixed-gender collaborations in teaching not explained by unobserved differences across fields or institutions.

Our analysis further reveals a significant and strong association between the gender composition of a teaching team and the course's interdisciplinarity, with mixed-gender teams being more interdis-

ciplinary than all-male teams or courses taught by individual instructors. This evidence suggests that gender diversity can be a potential lever for increasing interdisciplinary teaching in tertiary education.

We also find a significant association between team configurations and the fraction of cited female authors. Specifically, classes taught by a female instructor alone tend to cite a higher fraction of female authors than those taught by male instructors, with mixed-gender teams falling in between. This finding highlights teaching practices as an understudied potential driver of women's underrepresentation in academia. Finally, we observe a trend toward novelty: female instructors assign more recent readings than their male counterparts, regardless of team size, but mixed-gender teams tend to cite more conventional readings and are less likely to cite cutting-edge research. This evidence contributes to the debate on the factors shaping the education-innovation gap (10).

2 Literature

Research shows that gender and institutional structures shape key aspects of academic work, from team formation to curriculum design. Four strands of this literature are particularly relevant to our study: (i) research on how gender influences collaboration patterns, (ii) the representation of women in course materials, (iii) the interdisciplinarity of mixed-gender teams, and (iv) the propensity of such teams to innovate. These insights provide the conceptual foundation for our study, which we review in detail below.

2.1 Gender and team formation in academia

Teams play an increasingly important role in knowledge production (12, 13), and a large body of literature documents strong *gender homophily* in scientific collaboration and professional networks (14). Scholars in economics, the life sciences, and many other fields tend to co-author disproportionately with same-gender colleagues (15–18). Notably, this form of gender-based sorting is not merely driven by institutional constraints: it appears even in large and diverse research environments (e.g., 18) and across career stages (e.g., 19). Such gender homophily is also considered a contributing factor to gender gaps in outputs (e.g., 20) and to broader gender inequalities in academia (e.g., 15).

While research collaborations have been widely investigated, collaboration patterns in teaching remain less well understood. On the one hand, homophily may shape teaching teams by reflecting the same individual preferences observed in research collaborations. On the other hand, teaching has distinctive features: its predominantly local and in-person nature could either constrain or amplify gender-based homophily. These considerations motivate our effort to explore the prevalence and gender composition of teaching teams at scale.

2.2 Representation of Women in Citations and Course Materials

A substantial body of research examines gender differences in citation patterns (20–23), driving factor of the persistent gender bias in academia (24). Citation practices often reflect gender homophily (e.g., 23), and male-dominated fields may confer a "first-mover advantage" on men (e.g., 25). Other contributing factors include different self-citation patterns (22) and overall gaps in publication output (20).

Evidence that these disparities extend into teaching is more limited, but studies indicate that female scholars are underrepresented in course syllabi (26–28). This underrepresentation appears linked to the instructor's gender. For example, in Political Science, instructors' gender predicts the assignment of female-authored readings, suggesting a form of gender homophily in course content (29). Similarly, in research on political science, (21) finds that female-led teams cite more women than male-led teams, whereas mixed-gender teams do not cite more women than all-male teams. These findings suggest that team composition and dynamics strongly influence decisions about what to cite or include in course readings. A key goal of our study is to investigate these patterns on a large scale across multiple domains and institutions.

2.3 Mixed-Gender Teams and Interdisciplinarity

Another relevant strand of literature concerns the drivers of interdisciplinary work in research. Recent evidence suggests that women, on average, undertake more interdisciplinary research than men (30), and that interdisciplinary collaborations can produce broader scientific outcomes (31). Taken together, this work suggests that the presence of women in a team is associated with more interdisciplinary intellectual contributions.

In a teaching context, however, other factors may influence this relationship. For example, being interdisciplinary in research does not necessarily translate into interdisciplinary teaching styles. Furthermore, students may not demand interdisciplinary courses. Or there might be institutional constraints that prevent programs from supporting interdisciplinarity. Finally, team dynamics or matching patterns may prevent instructors from finding good partners for interdisciplinary courses. To shed light on these issues, we explored, at a large scale, the relationships among course interdisciplinarity, team size, and gender composition in teaching.

2.4 Gender Diversity and Innovation

Extensive research has shown that gender-diverse teams tend to generate more novel and higher-impact ideas than single-gender teams in scientific collaboration (e.g., 32). Related work on research and R&D teams links gender diversity to more radical or innovative outputs, as well as to improved decision-making and performance (33–37).

However, in the context of teaching, the relationship between gender diversity and "novelty" is less well understood. A key challenge lies in defining measures of novelty in a pedagogical setting. First, syllabi often rely heavily on textbooks rather than on journal articles, and pedagogical innovation may lag behind the scientific frontier. Moreover, innovation in teaching can take different forms: instructors can adopt new methods that are pedagogically novel but not at the scientific frontier ("teaching novelty"); they can assign more recent materials ("recency"); or they can include papers at the forefront of research ("scientific novelty"). In this study, we propose simple measures to begin empirically exploring these three dimensions at scale.

2.5 Covid-19's impact on academic work

COVID-19 disrupted academic work, reducing research time and scientific output, with particularly strong effects for women and researchers with caregiving responsibilities (11, 38–41). At the same time, the pandemic also reshaped collaboration networks and scientific meetings: studies report a decrease in new co-authorships (39) and an increase in cross-border teaming (42), and a shift towards virutal conferences and online meetings. While online formats broadened participation,

with a modest increase in women's representation (43), they also reduced opportunities for informal, in-person interactions that are seen as vital for collaboration and idea generation (44). In parallel, universities were forced into a rapid transition to online and hybrid teaching, potentially altering how teaching teams are formed and how often instructors collaborate across gender and disciplinary boundaries. We therefore exploit the onset of COVID-19 as an exogenous shock and estimate trends around 2020 to examine whether the prevalence and composition of mixed-gender teams changed after the pandemic, conditional on institution and field.

3 Materials and Methods

3.1 Data sources

3.1.1 Open Syllabus corpus

The core dataset consists of a corpus of more than six million university syllabi compiled by Open Syllabus (New York, US) through web extractions from university websites. These extractions identify syllabi with a median confidence level of 99.8%. A tagging algorithm extracts key course details, such as the title, description, academic year, language, a list of anonymised instructors, and the assigned readings.[1] OpenSyllabus also assigns each syllabus to one of 69 top-level disciplinary fields, derived from the U.S. Department of Education's CIP classification system.[2]

While the original dataset includes syllabi in 49 languages, most documents (96%) are in English. For simplicity, we focused exclusively on English-language syllabi.[3] This choice resulted in a total of 5.4 million syllabi (1990-2019) from approximately 4,000 higher education institutions across fifteen countries (Table SI-1).

Because course level (e.g., undergraduate or graduate) was not explicitly reported in the data, we inferred it from course codes. For example, "Psychology 101" typically denotes an introductory course, whereas "Psychology 401" indicates a more advanced offering. Using this heuristic, we categorized syllabi into four levels: basic, advanced, graduate, or unknown (see Section SI-1.2 for the details).[4]

3.1.2 Instructor genders

Each syllabus lists one or more instructors, with 76% listing a single instructor, 16% listing two, 4% listing three, and 4% listing more than three instructors. For each syllabus, OpenSyllabus automatically determines the instructors' gender based on their names. This gender disambiguation process employs state-of-the-art methods that have been shown to achieve high accuracy on other datasets (e.g., 21), which are detailed in the Supplementary Information (Section SI-1.1). In our dataset, this classification resulted in 52% male, 37% female, and 11% unknown categories.

[1] Documentation available at: https://docs.opensyllabus.org

[2] The CIP classification is available at: https://nces.ed.gov/ipeds/cipcode/browse.aspx?y=55

[3] Our focus on English-language courses means that, while we have comprehensive data for English-speaking countries such as Canada, Ireland, the United States, and Great Britain, the sample in non-English-speaking countries tends to be more representative of internationally oriented universities. These are typically institutions offering programs in English or advanced-level courses, such as postgraduate programs or disciplines where English is the primary medium of instruction within traditional universities.

[4] According to (10), this classification procedure is approximately 85% accurate for a sample of U.S. courses that could be matched to catalogues with verifiable information.

(Table SI-4 illustrates the gender composition of the teaching teams). After excluding syllabi with unknown gender, the distribution was 58% male and 42% female instructors.

These figures broadly align with the 45% of female academic staff reported in OECD countries (45). Although official statistics to assess the representativeness of this gender population are not available, a detailed comparison with official statistics (Supporting Info, Section SI-4) shows that the observed trends in the proportions of women and men are highly correlated with representative statistics on academic staff across countries and with the distribution of graduates across fields (used as a proxy for the number of instructors). This analysis indicates a reasonable representativeness of our data.

3.1.3 Linking syllabi to bibliometric data

About 2.9 million syllabi (53% of the total) list readings matched with bibliographic sources, providing additional metadata on authorship, journal of publication, and publication year. Institutions are matched to a list of more than 22,000 entities from the Research Organisation Registry (ROR), providing further metadata on institutional characteristics, including country and enrollment figures. Overall, the institutions in our sample account for over 35 million enrolled students today.[5]. Overall, our dataset captures roughly 50% of the educational institutions listed in ROR, underscoring its broad coverage.[6]

To assess the scientific novelty of the readings assigned in each syllabus, we further linked the data to SciSciNet (v2) (46), a large-scale database of scientific publications that includes pre-computed indicators of novelty, such as the atypicality measure introduced by Uzzi et al. (47). Matches were performed using article DOIs. Unfortunately, most syllabi include textbooks that do not have a DOI and a corresponding atypicality measure. Even so, the process resulted in a match with 80% of all readings with at least an available DOI in the readings. These matched publications appear in roughly 400,000 syllabi, representing about 14% of the 2.9 million syllabi containing reading lists.

3.1.4 Supplementary Covid-19 dataset

To examine changes associated with the Covid-19 lockdown period, we supplement this dataset with a second corpus consisting of 2.2 million syllabi of courses between 2019 and 2023 from 33 European countries (EU-27 plus Switzerland, Norway, Iceland, the United Kingdom, and Liechtenstein).

3.2 Outcome variables

Building on prior research highlighting the value of exposing student to cutting-edge knowledge (10), the influence of interdisciplinary training on career outcomes (3), and evidence of gender disparities in academic recognition (48–50), we focus on a set of outcome variables designed to capture these dimensions of the assigned readings and course content. These variables allow us to examine how team configurations, including gender composition and team size, are associated with the interdisciplinarity of assigned readings and their key characteristics, such as publication

[5]For more details on how OpenSyllabus classify and match the data, the related documentation is available online at https://docs.opensyllabus.org.

[6]The same methods used to identify the gender of the instructors were used for the gender of the authors listed in the readings, resulting in 32% female and 56% male authors, with 12% of the authors having an unknown gender.

age and the inclusion of female-authored works. The outcome variables are described in detail below; a concise summary is in Table 1.

3.2.1 Interdisciplinarity

We measured interdisciplinarity by analysing course descriptions from syllabi, following Evans et al. (3, 51). This approach converts course descriptions into "bags of words", where word frequencies are normalised by the inverse ratio of term frequency to document frequency (TF-IDF). We then computed a correlation matrix of word usage across academic fields to quantify the conceptual distances between them. The interdisciplinarity score for each syllabus was calculated as a weighted average of pairwise correlations with other syllabi, with weights reflecting field distance (see Section SI-1.3). This method ensures that syllabi associated with distant fields, either academically or conceptually, are considered more interdisciplinary.[7]

We expressed interdisciplinarity for each syllabus i as the percentile rank within each academic year of the interdisciplinarity score:

$$\text{Interdisciplinarity}_i = \text{PR}_{yr}(\text{Interdisciplinarity Score}_i),$$

Where PR_{yr} represents the percentile rank function applied to all syllabi within a given year yr. This normalisation controls for skewed score distributions and allows comparison across years.

3.2.2 Recency, Conventionality, and Atypicality of the Readings

To characterise the novelty of the assigned readings, we used three key dimensions: (1) the publication year of the assigned readings (2) the frequency of new articles or books introduced in the syllabus; and (3) the median scientific novelty of the readings as measured by the Uzzi et al's atypicality measure (47).

First, we define the total number of references, N_i, as the sum of articles, books, and chapters listed in a syllabus i. This variable serves as a broad measure of a course's "breadth," as more assigned readings may indicate a more extensive or comprehensive curriculum. Then, we define the *Age of Readings* variable as the difference between the syllabus year (Year_i) and the average publication year of the assigned readings $k = 1, \cdots, K$:

$$\text{Age of Readings}_i = \text{PR}_{yr}\left(\text{Year}_i - \sum_{k=1}^{N_i} \text{Publication Year}_k / N_i\right),$$

Where PR_{yr} represents the percentile rank function applied to all syllabi within a given year yr. This variable provides a proxy of how recent, or "novel," the readings are.

Second, to capture the conventionality of the readings, we compute the *Share of Conventional Readings* as the proportion of references in syllabus i that appear in any earlier iteration of the same course (as observed in our dataset). This measure reflects how frequently instructors refresh their syllabi by incorporating newly selected books or articles, which is an important dimension of curricular innovation that is not captured by publication dates alone.

[7] To scale to millions of documents, we used random subsampling of academic fields over years and averaged results across subsamples for robustness, as outlined in Section SI-1.3.

Third, to quantify the scientific novelty of the assigned readings, we use the median atypicality score of all references in syllabus i. Atypicality, introduced by Uzzi et al. (47), measures how unexpectedly different a paper's combination of prior knowledge is relative to conventional citation patterns. We rely on the pre-computed atypicality values provided in SciSciNet (v2) by Lin et al. (46). Higher values indicate that the readings draw from more unconventional or cross-disciplinary combinations of ideas, offering a complementary dimension of novelty that is orthogonal to recency or syllabus updating.[8]

Together, these three measures, recency of publications, the conventionality of readings, and the scientific atypicality of the readings, provide a multidimensional characterisation of curricular novelty.

3.2.3 Women Authors Cited

Finally, we define the *Ratio of Female Authors* as the proportion of female authors among all authors in the assigned readings:

$$\text{Ratio of Female Authors}_i = \frac{\text{Female Authors}_i + 1}{\text{Female Authors}_i + \text{Male Authors}_i + 2}.$$

Here, we add two pseudo-observations (one for each gender) to stabilise the ratio, preventing extreme values in cases with very few authors (52). This metric enables us to examine whether gender and collaboration are associated with the representation of female-authored work in teaching.

3.3 Simulating Teaching Collaborations

Building on previous research showing that gender-diverse teams are underrepresented in science (53), we investigate the evolution of the gender composition of co-teaching teams to determine whether it deviates from what is expected under a gender-neutral matching process. Crucially, this analysis accounts for the fact that team formation is influenced not only by individual preferences but also by institutional factors, such as departmental affiliation or academic field, as co-teaching typically occurs among faculty within the same department or the same academic field. To account for these institutional constraints, we employ a Monte Carlo randomisation approach adapted from Uzzi et al. (47, 53). This approach preserves the overall gender composition and team size distribution while randomly reassigning instructors within strata defined by institution, field, and academic year. This simulation generates a randomised network in which instructors form teams independently of gender while maintaining the underlying institutional and disciplinary constraints. Therefore, by comparing actual data against teams formed in the randomised network, we can assess the difference between the observed team gender composition in the data and a counterfactual situation where instructors formed teams in a gender-neutral manner. See the details in the Supplementary Information (Section SI-2).

[8] Note that this measure only captures the atypicality at the time of publication, hence, it may not entirely reflect the atypicality at the time of the course. This issue can be partly accounted for in the analysis by (1) aggregating over multiple readings and (2) controlling for the average publication year of the readings or alternatively by imposing a discount for articles published beyond a certain threshold from the course date (e.g., imposing a mean atypicality for readings five years or more older than the course year).

3.4 Regression analysis

To evaluate the association between gender composition, team size, and course content, we define four teaching team configurations, $j \in \{F, M, MM, MF/FM, FF\}$, where F and M denote female and male instructors teaching alone, respectively. MM represents two male instructors; FM/MF indicates mixed-gender pairs; and FF corresponds to two female instructors. We then employ regression analysis to study the association between these team configurations and course outcomes across academic years, $t = 2000, \cdots, 2019$. As discussed before, the outcomes of interest include (1) interdisciplinarity, (2) the average age of readings, and (3) the proportion of cited female authors. To estimate these effects, we employ the following linear mixed-effects model:

$$Y_{j,t} = \alpha_t + \text{Team}_{j,t} + \text{STEM}_t + \eta_{f,t} + \text{Country}_t + \text{CourseLevel}_{l,t} + \delta_t + \epsilon_{j,t}.$$

Where:

- $Y_{j,t,f,c,s}$ is the outcome variable for team configuration j in year t, field f, and school s,
- α_t is a fixed effect for the academic year t,
- Team$_{j,t}$ is a fixed effect for team configuration j in year t,
- $STEM_t$ is a fixed effect for STEM courses in year t,
- $\eta_{f,t}$ is a random intercept for academic field $f = 1, \cdots, 69$ at year t,
- Country$_{c,t}$ is fixed effects for the institution s's country c in year t,
- CourseLevel$_{l,t}$ is an effect for the level of the course (l = basic, advanced, graduate, unknown) at year t,
- $\delta_{s,t}$ is a random intercept for each of approximately 4000 unique institutions,
- $\epsilon_{j,t}$ is the residual error term.

Together, the model allows us to examine the association between teaching team configurations and citation-related course outcomes while accounting for potential confounding factors across disciplines and institutions.

4 Results

Figure 1 illustrates gender composition and team size trends in university courses for single- and two-instructor courses (2000-2019). Panel A shows a decline in male-only single-instructor courses, from approximately 60% in 2000 to 46% in 2019, alongside an increase in female-only single-instructor courses, from roughly 25% to 36%.[9] Panel B shows male-only two-instructor courses also decreased, from about 8% in the early 2000s to 6% in 2020, while female-only and mixed-gender two-instructor courses remained relatively stable, each accounting for approximately 4% and 3%, respectively. These patterns indicate a consistent shift toward greater gender diversity in course instruction over time, with mixed-gender teaching teams (3%) consistently less common than same-gender teams (10%).

[9]This overall trend aligns with the increase in women holding academic positions worldwide. In 2000, women comprised approximately 35% of the global academic staff. By 2022, this figure had risen to about 44%, according to data from the World Bank. The data are available at: https://data.worldbank.org/indicator/SE.TER.TCHR.FE.ZS

To assess whether gender imbalances in co-teaching teams persist after accounting for institutional constraints across fields and institutions, Figure 2 compares observed teaching team compositions (2000–2019) with those generated by a gender-neutral Monte Carlo simulation. This model randomly shuffles instructors while preserving the overall distribution of course loads per year by institution and academic field but ignoring gender-based preferences or constraints (see Section 3).

The results reveal that actual data systematically deviate from simulated expectations: same-gender teams, such as female-female (FF) and male-male (MM) courses, occur *more* frequently in actual data than in simulations by 66% and 20%, respectively, in 2019. By contrast, mixed-gender collaborations (MF/FM) are consistently *underrepresented* in the actual data (3%) compared to simulations (6%). These findings suggest that significant social or institutional dynamics—beyond chance—reinforce same-gender pairings, especially among women. Such dynamics may include gender-based homophily, mentoring networks, or within-department barriers or assignment practices.

Figure 3 disaggregates the comparison between actual and simulated mixed-gender (MF/FM) courses by academic field. Nearly all fields exhibit a stark underrepresentation of mixed-gender teams (relative to expectations) by a factor of two to four times. For instance, in Medicine (Health and Welfare), the actual share of mixed-gender collaborations is 4.8% compared to an expected 9.1%, indicating a significant imbalance. Similar gaps are evident in Law (3.8% actual vs. 6.4% simulated) and Linguistics (4.3% vs. 6.7%), underscoring the pervasiveness of barriers to mixed-gender teams across various academic fields. Remarkably, we observe no differences in these patterns between male-dominated and female-dominated fields (e.g., Engineering or Accounting vs. Nursing or Chemistry), suggesting that the underrepresentation of mixed-gender teams may be a structural feature rather than one driven by field-specific gender imbalances.

Figure 4 illustrates that the proportion of mixed-gender teams in the simulations consistently exceeds the observed proportions across various geographic regions, despite notable variations in the magnitude of these differences. In 2019, for example, mixed-gender teams are relatively rare in Great Britain (1%) compared to Canada (4%). However, in the simulations, the proportion of mixed-gender teams in both countries increases substantially, 1% to 3% and 4% to 5%, respectively. In 2019, the most considerable discrepancy between simulated and observed proportions is in EU countries, where it ranges from 5% to 12%. Overall, these patterns underscore the robustness of the findings across diverse geographic contexts.

4.1 Analysis Pre- and Post- COVID-19 in Europe

Using a recent dataset of 2.2 million European syllabi from 2017–2022, we examine how the composition of teaching teams changed before and after the COVID-19 pandemic. Across countries and academic fields, the total number of courses declined sharply in the post-COVID period (Figure SI-3, in SI). However, regression analyses reveal that the magnitude of this decline differed substantially depending on the gender composition of instructors (Figure 5). After COVID-19, the share of single-instructor courses fell by more than 26%, a significant and substantial drop relative to the pre-pandemic period. Within multi-instructor teams, the proportion of mixed-gender collaborations decreased by up to 10%. Finally, among single-instructor courses, the share of women instructors declined by approximately 1% relative to men. Taken together, these results highlight that single-instructor courses declined more sharply than collaborative ones, and that among collaborative teams, mixed-gender groups were disproportionately affected by the pandemic. Women

were also slightly more likely to reduce their participation, although this effect is modest in size.

Figure 6 shows the results of our Montecarlo simulations for this dataset. As highlighted in the previous analysis, there are disproportionately fewer mixed-gender teams than one would expect under gender-neutral matching. However, post-Covid, the gap appears to widen substantially in 2022. This pattern indicates that the pandemic, particularly the lockdown measures implemented across Europe, may have significantly hindered the formation of mixed-gender teaching teams.

4.2 Associations Between Teams and Course Content

To examine how teaching team size and gender composition are associated with important aspects of course materials, we analyse three key metrics: the percentile rank of the interdisciplinarity score per year ("interdisciplinarity"), the average publication year of the readings ("age of readings"), and the share of female authors cited in the assigned readings ("share of female authors"). As previously discussed, we employ linear mixed-effects regressions to examine these relationships while accounting for unobserved differences across academic fields, institutions, time, and other relevant covariates.

4.2.1 Interdisciplinarity

Figure 7 illustrates the evolving variation in interdisciplinarity across different team configurations, accounting for unobserved effects for academic field and country. When teaching alone, our analysis reveals little differences in interdisciplinarity between female and male instructors. However, in recent years, female instructors have increasingly taught significantly more interdisciplinary solo courses. By contrast, mixed-gender consistently exhibit higher interdisciplinarity compared to all-male teams. As the figure illustrates, in most years, the difference between mixed-gender and male-alone courses is statistically significant ($p < 0.05$), and teams with two male instructors tend to be less interdisciplinary than solo-male courses. Notably, we find no significant evidence of a difference between mixed-gender and teams with two female instructors. These results point to a robust association between gender diversity and interdisciplinarity.

4.2.2 Citing Women Authors

Figure 8 highlights significant and persistent gender association with the percentage of female authors over total authors cited in course readings per year, controlling for academic field and country.[10] All-female courses consistently cite a higher fraction of female authors than all-male ones in the same year, with an effect that decreases over time, going from 8% in 2000 to 4% in 2019, with minor or insignificant differences between courses taught by one vs. two instructors. Mixed-gender courses are in between, as they cite a larger share of women than all-male courses but less than all-female courses. Overall, these results indicate a consistent association between gender and cited patterns, suggesting that readings tend to cluster based on the gender of the instructors, and mixed-gender teams could promote greater diversity in assigned readings.

[10]This analysis excludes syllabi with no matched readings with the available bibliographic sources and, within the matched readings, excludes the references where the authors' gender remained unidentified.

4.2.3 Teaching Conventionality, Age of Readings, and Scientific Novelty

Figure 9 reveals persistent temporal trends and significant gender differences in the publication age of the selected readings, even after accounting for observable differences across multiple dimensions, including course level, academic field, institution, and country. Course taught by a single female instructor tend to assign more recent readings than comparable courses taught by a single man instructor (the reference category), with the difference going from -3% in 2000 to -1% in 2019. Similarly, courses led by two women also assign newer material than those taught by two men. Mixed-gender teams generally assign more recent readings than single-male instructors, although less than all-female teams of equal size. No significant differences emerge between courses taught by two male instructors and the single-male baseline. Overall, these findings indicate that the presence of women in teaching teams, either alone or with a male co-instructor, is associated with more recent readings, although the gender effect appears to decrease over time.

Figure 10 illustrates significant gender differences in the readings' conventionality, which is the median citations of syllabus readings from references in other syllabi. Team-taught courses tend to be more conventional than single-instructor courses, as both mixed-gender and all-male teams exhibit significantly higher conventionality than the baseline, while the difference with two-women teams is insignificant. Courses taught by women alone are significantly less conventional than those taught by men alone, but the difference is small (less than 1 pp). Taken together, this evidence indicates a strong association between reading conventionality and teaching in teams with more than one instructor, which is partly offset by the presence of women.

Figure 11 presents the results of our analysis of the scientific novelty of the readings, based on approximately 400,000 syllabi for which we obtained Uzzi et al. (47)'s atypicality measure precomputed by SciSciNet (v2) (46). Controlling for field, course level, and other relevant characteristics, the results indicate that readings produced by mixed-gender teams are significantly less at the frontier of knowledge.[11] Similarly, women-led teams show a negative association compared to man-teaching-alone courses, with the effect being stronger in courses taught by two women. In other words, men-only teams exhibit slightly higher atypicality in our dataset than any other team configuration.

4.3 Heterogeneity

Figure 12 highlights several key differences between STEM and non-STEM fields, based on separate models estimated for STEM fields compared against results from the full sample.[12]. The gap in female-author citations associated with women instructors remains consistent but is significantly smaller in STEM fields, roughly half the size observed in all fields. The positive association between mixed-gender teams and conventional readings is larger in STEM fields. Conversely, the gap in atypicality widens for women teaching alone, although the effect has been diminishing over time. In contrast, the gap in the age of assigned readings between women and men teaching alone is smaller in STEM. With respect to interdisciplinarity, the estimated differences are small and not consistently significant across years. As a result, the evidence for heterogeneity in interdisciplinarity within STEM is inconclusive.

[11] This regression also inclused the age of readings as a control for the novelty at time of publication of the article.

[12] We converted CIP fields into ISCED-F broad categories and considered STEM the following: (1) Natural Sciences, Mathematics, and Statistics, (2) Information and Communication Technologies (ICTs), and (3) Engineering, Manufacturing, and Construction.

We have also explored heterogeneity across countries by fitting separate models for the US and comparing the results against the estimates from the full sample. The analysis revealed no significant differences for the US-based regressions (Figure SI-4, SI). Therefore, our study provides no evidence of cross-country differences in the observed associations.

4.4 Robustness

The robustness checks conducted, as detailed in the Supplementary Information (Section 4.4), show that the main results are consistent across multiple alternative analyses. These included mixed-effects regressions on the full dataset, log-transformations of key dependent variables, quasi-Poisson models for counts of female authors, trimming outliers, and testing different specifications related to instructor composition and seniority. Across all these variations, the findings remained broadly stable, demonstrating that the results are not sensitive to specific modeling choices or data subsets.

5 Discussion

5.1 Summary of the findings

Our analysis of approximately five million syllabi from over 4,000 universities in fifteen countries reveals several key findings. First, while the share of classes taught by female instructors has been increasing over the last twenty years, the fraction of mixed-gender co-teaching classes has remained consistently low (3%) and significantly below that of same-gender teams (10%). This trend can stem from a lack of gender diversity in specific fields or from administrative practices that limit opportunities to form mixed-gender collaborations. However, it can also arise from gender preferences in team formation, whereby instructors tend to form teams with same-gender partners ("homophily"), a tendency already observed in research collaborations and other academic domains (e.g., 18).

Our analysis shows that the underrepresentation of mixed-gender teams persists even after accounting for unobserved differences across fields, institutions, and academic years. Specifically, employing Monte Carlo simulations that randomly form teams in a gender-neutral manner, our analysis controls for typical institutional constraints, such as maintaining constant course loads across institutions and 69 academic fields within a given year. By comparing simulated to actual teams, we find that instructors tend to partner with same-gender colleagues more than twice as expected between 2005 and 2019. This result is robust across academic fields, although it is more pronounced in specific fields (Chemistry, Business, Medicine). Additionally, the underrepresentation of mixed-gender teams is consistent across countries, with the greatest effect in EU countries, where only 5% of courses are taught by mixed-gender teams, compared to an expected 12%.

Additional insights emerged from the analysis of team patterns before and after the COVID-19 pandemic (2017-2022) across thirty-three European countries. First, the pandemic caused a general decline in the number of courses, consistent across fields and countries, but this decline was disproportionately concentrated among individual instructors rather than collaborative teams. This finding likely reflects the reduction in in-person course offerings, which were primarily taught individually. Second, although collaborative teams were relatively less affected by the overall drop in courses, mixed-gender teams declined disproportionately. Taken together, these findings suggest

that the formation of mixed-gender teaching teams depends more on in-person interactions than other types of teaching collaborations.

Our analysis further highlights how different team configurations are associated with key aspects of teaching: (i) mixed-gender teams tend to be more interdisciplinary than all-male teams, (ii) all-female teams tend to assign more recent readings, (iii) mixed-gender teams tend to cite more "conventional" readings (i.e., those cited in other syllabi before) and less at the frontier of scientific research (i.e., lower mean atypicality) and (iv) mixed-gender teams tend to cite a higher share of female authors than all-male teams, but less than all-female teams. These associations are not driven by unobserved differences across fields, course levels, institutions, and years that we account for in the regressions. Furthermore, these findings expand existing literature in the following ways.

5.2 Main Contributions

First, our findings on team formation extend prior research on academic collaboration, which has traditionally focused on research partnerships (12, 17, 32, 53, 54), to the domain of teaching. The significant gender patterns and underrepresentation of mixed-gender co-teaching teams echo the literature on homophily and bias in team formation within research collaborations (e.g., 18) and underscore the critical role of gender dynamics in shaping not only scientific production but also pedagogical practices. Moreover, by combining analysis of a massive syllabi dataset with Monte Carlo simulations of gender-neutral team formation, our findings show that these patterns cannot be explained solely by country-level, institutional, and field-specific factors, such as cultural barriers or gender imbalance in specific fields. This evidence highlights the need to investigate these gender dynamics further, focusing on the underlying causal mechanisms that limit gender-diverse collaborations in teaching, a critical direction for future research.

Secondly, building on prior research that measures interdisciplinary curricula (51) and examines their effects on student outcomes (3), our study shifts the focus to the drivers of interdisciplinarity, linking it to the size and gender composition of teaching teams. While we find only minor and inconsistent gender differences in solo-taught teams, interdisciplinarity significantly increases in mixed-gender teaching teams. This effect is associated with the presence of women collaborators, who tend to be more interdisciplinary when working in teams. These findings extend the literature that compares interdisciplinarity between men and women in academic research (30) to the teaching domain, establishing a novel connection between gender diversity and interdisciplinary teaching practices. This connection highlights a potential lever for universities and academic institutions seeking to foster interdisciplinarity in their curricula.

Thirdly, our study advances our understanding of the determinants of gender disparities in academic recognition by extending the focus beyond scholarly citations to teaching materials. While prior research has predominantly focused on gender citation gaps in academic publications (e.g., 21), our study demonstrates the critical role of gender dynamics in the content presented in class and assigned readings. More specifically, our findings align with prior research on gendered citation patterns in the academic literature (e.g., 21), which shows that female scholars are more likely to cite work by other women. Interestingly, Dion et al. (21) finds that mixed-gender research teams do not cite more women than male-only teams, highlighting a divergence from our course-level results. This finding indicates that instructor gender shapes reading lists in ways that may differ from research citation patterns and that mixed-gender teaching teams could foster greater gender diversity in assigned readings. Together, these findings suggest new potential drivers of gender

stereotypes in academia (49), underscoring the need to broaden research on the causal mechanisms underlying gender disparities in citation practices to include teaching contexts, thereby moving beyond the current emphasis on scholarly citations alone.

Finally, our findings reveal a persistent gender-based pattern in the assignment of novel materials, with female instructors tending to include more recent content in their syllabi than male instructors. In contrast, mixed-gender teams—or teams in general—tend to assign more conventional readings and cite scientific articles with lower atypicality. This evidence points to a complex relationship between team composition and teaching innovation that warrants further investigation. One possible explanation is that female instructors may assign more recent readings because they enter the profession more recently, which could account for a weakening association between instructor gender and recency over time. Similarly, mixed-gender teams may rely on less atypical or more conventional readings because instructors from different fields must establish a shared foundation rooted in classic works. Taken together with our previous finding that interdisciplinary content is more common in mixed-gender teams, these results suggest that interdisciplinary courses may inherently require more conventional readings to bridge disciplinary differences.

Overall, unveiling these associations contributes to understanding the observed gender-innovation gap in tertiary education (e.g., 10). However, while our results suggest a strong gender association, they remain inconclusive regarding its underlying drivers, whether the pattern reflects gender per se or is confounded by age or career stage (e.g., younger vs. female instructors). Notably, this trend coincides with the growing presence of women entering academia during the study period, suggesting that newer instructors may play a key role in pushing curricular boundaries. Nonetheless, further research is needed to disentangle the influence of gender from other intersecting factors, such as cohort effects, field-specific norms, and institutional context.

5.3 Limitations

Our analysis bears several limitations. First, the dataset does not include granular information on the course's subfields that go beyond the 69 top-level fields identified in the dataset. If male and female instructors tend to concentrate on different subfields (e.g., Econometrics and Macroeconomics, within Economics), the observed underrepresentation of mixed-gender teams may reflect limited availability of instructors of the other gender in the subfield, especially for advanced courses where teaching teams are more likely to form around narrower areas of expertise. This limitation prevents disentangling the exact driver of mixed-gender underrepresentation, which can derive from gender-based preferences towards subfields, limiting availability, or a tendency to seek same-gender partners or homophily. Further research is needed to fully disentangle these underlying mechanisms.

Second, our data lack characteristics that operate within institutions, such as instructor experience or academic rank. Hierarchical differences or administrative structures may contribute to the observed gap in cross-gender collaborations — for example, by making newly appointed female instructors less likely to be selected by higher-ranking male instructors. However, our results show that the under-representation of mixed-gender teams persists even when co-teaching teams are disaggregated by male- and female-led courses (as measured by syllabus order), demonstrating that the trend holds regardless of hierarchical differences. Therefore, while we cannot entirely exclude other institutional constraints, the observed gap in mixed-gender teams likely reflects strong gender-based homophily.

Third, our measurement of novelty in syllabi is constrained by the limited citation base typical of

course materials and the temporal mismatch between publication-time novelty and the novelty students experience during instruction. These factors limit our capacity to apply systematically standard novelty metrics to teaching materials (e.g., 47). Yet, by combining multiple measures, our work provides a viable path to characterise the multidimensional nature of innovation in teaching using syllabi data.

Fourth, institutional policies regarding teaching loads and the recognition of co-teaching vary substantially across countries and institutions. In many universities, team teaching does not fully count toward teaching loads or is treated as an overload, limiting faculty opportunities to engage in it even if they wish to. Moreover, teaching teams are not always determined by individual instructors' preferences: in many institutions, course assignments and team composition are partially or entirely determined at the departmental or program level—for example, by course coordinators, curriculum structures, or administrative rules. In such cases, team formation may reflect institutional or organizational preferences rather than instructors' choices. Our data do not capture these institutional constraints or assignment mechanisms, which may mechanically reduce or shape the observed incidence of mixed-gender teams. Consequently, our descriptive patterns reflect both individual preferences and the structural opportunities and assignment practices provided by institutions.

Finally, although our data covers 50% of educational institutions in the selected countries, and comparisons with official statistics on the distribution of academic staff and US graduates by field show a reasonable alignment with the trends observed in our sample, it is important to note that the sample is not fully representative of the underlying population. Additional research is needed to validate our results with appropriate weights or samples of the full population.

5.4 Conclusion

Overall, this study offers critical insights into the academic market. As for research teams, teaching teams can impact instructors in multiple ways. First, junior faculty may have access to the experience and advice of senior faculty, which could increase their chances of promotion. Secondly, diverse teaching teams may inspire research collaborations, including interdisciplinary work. Finally, teaching assistants can actively seek out mentors and may benefit from these collaborations when applying for PhD programs or entering the labour market. Therefore, understanding how teaching teams are formed can help explain career trajectories.

Figure 1: Evolution of Teaching Teams by Gender Composition and Size. Trends in course gender composition from 2000 to 2019 reveal a steady increase in women's participation (both in solo-taught and two-instructor courses), while the proportion of mixed-gender teams has remained relatively stable over time. (A) Percentage of solo-taught courses by instructor gender over time. (B) Percentage of two-instructor courses by gender composition over time. N = 5.1 million courses. The shaded area represents 95% confidence interval of the proportion per academic year.

Figure 2: Comparison of gender composition between actual courses and courses simulated with Monte Carlo. Simulations ensure gender neutrality while keeping constant institutional constraints (i.e., number of teams by size, institution, academic year, and 69 academic fields). Simulated mixed-gender teams consistently exceed observed proportions, highlighting persistent barriers to forming gender-diverse teaching teams.

Figure 3: This figure disaggregates the comparison of proportions between actual (green) and simulated (orange) mixed-gender (MF/FM) courses by academic field. The shaded bar indicates a 95% confidence level of the proportion.

Figure 4: This figure disaggregates the comparison of proportions between actual (green) and simulated (orange) mixed-gender courses (MF/FM) by country. Simulated mixed-gender teams consistently exceed observed proportions in all countries. EU countries are Austria, Denmark, France, Germany, Ireland, Italy, Netherlands, Poland, Portugal, Spain and Sweden.

Figure 5: Team composition post-Covid-19 change. Coefficients and 95% confidence intervals for post-covid period obtained from the following Binomial regressions: (a) probability of single teams being taught by a woman vs man; (b) probability of teams being composed by one instructor vs multiple (teaching collaboration); (c) probability of teaching teams being mixed-gender vs. same-gender collaborations. All regressions are based on 2.2M syllabi from institutions in thirty-three European countries (excluding teams with three or more collaborations, and authors of unknown gender).

Figure 6: Post-Pandemic Team Formation. Simulated gender-neutral vs observed teaching teams for 2.2M syllabi from institutions in thirty-three European countries. Covid-19 period highlighted (2020-2021). This shows that the gap between mixed-gender and same-gender collaborations widens after Covid.

Figure 7: Interdisciplinarity. Estimates and 95% confidence intervals for differences in Interdisciplinarity between courses taught by men alone (reference) and courses taught by other instructor teams. Interdisciplinarity is the percentile rank, within a given year, of a syllabus' interdisciplinarity score based on its textual description relative to other syllabi. Estimates are from separate mixed-effects regressions for each academic year, controlling for country, field, institution, course level, probability that the document is a syllabus, and number of readings, with weights proportional to the square root of the number of readings. Smoothed curves show local estimates averaged across years, weighted by the precision (standard errors) of the estimates.

Figure 8: Female-Authored Radings Ratio. Estimates and 95% confidence intervals for differences in Female-authored radings ratio between courses taught by men alone (reference) and courses taught by other instructor teams. This variable is the proportion of female authors cited in the course readings. Estimates are from separate mixed-effects regressions for each academic year, controlling for country, field, institution, course level, probability that the document is a syllabus, and number of readings, with weights proportional to the square root of the number of readings. Smoothed curves show local estimates averaged across years, weighted by the precision (standard errors) of the estimates.

Figure 9: Age of Readings by Team. Estimates and 95% confidence intervals for differences in Age of Readings between courses taught by men alone (reference) and courses taught by other instructor teams. Age of Readings is the percentile rank, within a given year, of a syllabus' average publication age of the readings. Estimates are from separate mixed-effects regressions for each academic year, controlling for country, field, institution, course level, probability that the document is a syllabus, and number of readings, with weights proportional to the square root of the number of readings. Smoothed curves show local estimates averaged across years, weighted by the precision (standard errors) of the estimates.

Figure 10: Readings Conventionality by Team. Estimates and 95% confidence intervals for differences in Teaching Conventionality between courses taught by men alone (reference) and courses taught by other instructor teams. Teaching Conventionality is the percentile rank, within a given year, of a syllabus' median citations of readings, based on references from other syllabi. Estimates are from separate mixed-effects regressions for each academic year, controlling for country, field, institution, course level, probability that the document is a syllabus, and number of readings, with weights proportional to the square root of the number of readings. Smoothed curves show local estimates averaged across years, weighted by the precision (standard errors) of the estimates.

Figure 11: Scientific Novelty by Team. Estimates and 95% confidence intervals for differences in Scientific Novelty between courses taught by men alone (reference) and courses taught by other instructor teams. Scientific Novelty is the percentile rank, within a given year, of a syllabus' median Uzzi et al's atypicality of readings, based on the combination of references in the readings. Estimates are from separate mixed-effects regressions for each academic year, controlling for country, field, institution, course level, probability that the document is a syllabus, and number of readings, with weights proportional to the square root of the number of readings. Smoothed curves show local estimates averaged across years, weighted by the precision (standard errors) of the estimates.

Figure 12: Heterogeneity within STEM Fields. Estimates and 95% confidence intervals for differences in (1) interdisciplinarity (2) readings' conventionality (3) age of readings (4) female-authored ratio and (5) readings' atypicality. Estimates are from separate mixed-effects regressions for STEM fields vs the full sample, in each academic year, controlling for country, field, institution, course level, probability that the document is a syllabus, and number of readings, with weights proportional to the square root of the number of readings. Smoothed curves show local estimates averaged across years, weighted by the precision (standard errors) of the estimates.

Table 1: Outcome variables

Variable	Definition
Course Interdisciplinarity	Percentile rank of the course's interdisciplinarity score for the year.
Age of Readings	Percentile rank of the average publication age of assigned readings.
Atypicality of Readings	Percentile rank of the median atypicality of assigned readings
Conventionality of Readings	Percentile rank of the median citation of the assigned readings as referenced in other syllabi
Ratio of Female Authors	Proportion of women authors in the assigned readings.

SI Supporting Information

SI-1 Data

SI-1.1 Gender disambiguation

OpenSyllabus uses a Python implementation of Genderize.io to estimate the probability that an author's name corresponds to a female gender.[13] Names with a predicted probability above 0.5 are classified as female; all others are classified as male. Prior research indicates that Genderize.io achieves high overall accuracy (92%) (55). In the context of academic authorship, a study hand-checking gender predictions in scholarly publications found that Genderize.io has an error rate of only about 2% (56). Despite this reliability, many instructors listed in syllabi provide only initials (e.g., "J." instead of "John" or "Jane"), which introduces ambiguity and increases noise in gender classification. To mitigate this, OpenSyllabus assigns an "unknown" category when an author's first name cannot be reliably determined.

SI-1.2 Course Level

To determine the level of each course listed in the syllabi, we first extracted the course codes for each syllabus (e.g., Psychology 101, Econ101). Then, we standardised all course codes by converting them to uppercase and removing any non-alphanumeric characters. From each cleaned code, we extracted the first sequence of digits and used the leading digit of this number as an indicator of course level. Codes beginning with 1 or 2 were classified as *basic*, those beginning with 3 or 4 as *advanced*, and those beginning with 5 or higher as *graduate*. Codes that did not contain a recognisable numeric component were assigned an *unknown* level. This approach enabled consistent categorisation across heterogeneous code formats. Furthermore, on a subset of 56,000 U.S. syllabi, prior work (10) showed that the course levels obtained using this procedure achieve an accuracy of 85% when compared with the official course levels listed in the corresponding catalog. This provides confidence in the quality of the classification for the U.S. context. For EU countries, no comparable benchmark currently exists.

SI-1.3 Interdiscipline Similarity

We measured interdisciplinarity using text similarity between syllabi as in (51) and (3). We transformed text from course descriptions into "bags of words," with term frequences (TF) normalised using the inverse document frequency (IDF). For each year, we calculated the TF-IDF scores for all syllabi and for 69 academic fields, using concatenated descriptions for the fields. We then computed the weighted average of the cosine similarity, $\cos(i, f)$, between each course i and field f, where the weight is based on the similarity between field f and the course's closest field f_{max}. Specifically, $w(f_{\text{max}}, f) = \cos(f_{\text{max}}, f)$, where f_{max} is the field that has the highest cosine similarity with course i (i.e., $f_{\text{max}} = \arg\max_f \cos(i, f)$) in that academic year.

Thus, the interdisciplinarity score for course i is:

$$\text{interdisciplinarity score}_i = 1 - \frac{\sum_{f \in (1,69)} \cos(f_{\text{max}}, f) \cdot \cos(i, f)}{\sum_{f \in (1,69)} \cos(f_{\text{max}}, f)}.$$

[13] See https://github.com/opensyllabus/osp-gender

To reduce computational costs, we "bootstrap" the field-by-field cosine similarity matrix by using a 10% random sample of syllabi for each academic year. We repeated the sub-sampling procedure ten times and averaged the results.

SI-2 Simulating Gender-Neutral Courses

We employed a simlar methodology to that developed by (47) for the analysis of academic citations. We counted the frequency of gender combinations (male-male, female-male, etc.) of each syllabus per field and academic year. We compared these combinations against those expected by chance, using a gender team composition network. In this network, for a given field, institution, and academic year, we switched all the instructors using a Monte Carlo algorithm. The switching algorithm preserves the total gender counts and the distribution of team size. This ensures that a course with n instructors in the original data will have the same number of instructors in the randomised network. Similarly, an institution with m male instructors and f female instructors teaching in a specific field will have the same number of male and female instructors. The only difference between the randomised and the original data will be the gender composition of the teams.

SI-3 Addtional Tables

In this section, we present additional descriptive statistics for the number of syllabi in each country SI-1, the distribution of syllabi per field SI-2, academic year SI-3, and teaching teams SI-4.

SI-4 Representativeness of the gender distribution

One potential concern for our analysis is the representativeness of the data. Our dataset covers several million courses and thousands of educational institutions, corresponding to about 50% of the educational organisations in the ROR, which makes the results interesting in their own right. Nevertheless, one may question how representative these data are of the broader population of instructors. Although we cannot directly test representativeness, we evaluate it in two ways. First, we examine whether the overall female-to-male ratio over time in each country correlates with OECD statistics on academic staff by gender. Second, for the U.S., we assess whether the sex ratio by field and year correlates with NCSES data on Ph.D. graduates by academic field, country, and year, which serves as a proxy for the maximum number of employable instructors.

As illustrated in Figure SI-1, our analysis of overall trends reveals a very high correlation for English-speaking countries (U.S. = .98, U.K. = .90), and greater heterogeneity for non-English-speaking countries, where representativeness is expected to be weaker given our focus on English-language syllabi. The analysis based on Ph.D. graduates similarly shows strong field-level correlations in many fields (Figure SI-2), such as in Natural Sciences (rho = .91), Social sciences and journalism (rho = .90), Education (rho = .77). However, there are fields with considerably lower correlation, such as in Health and welfare (rho = .14) or IT (rho = .29). This heterogeneity may stem from differences across disciplines in the proportion of Ph.D. graduates who remain in academia (e.g., biology has a comparatively high share of graduates who pursue careers outside academia). Nevertheless, these patterns suggest that, at least for English-speaking countries and in many academic fields, our data are reasonably representative.

SI-5 Pre-/Post- Covid-19 Patterns

Figure SI-3 illustrates pre-/post-pandemic patterns in the teams across academic fields.

SI-6 Heterogeneity: US vs non-US

Figure SI-4 illustrates heterogeneity in the associations between teams and outcomes within US courses and the other countries.

SI-7 Robustness Analysis

To ensure the reliability and robustness of our results, we conducted several additional analyses. In addition to reporting results from separate regressions on subsets of data by year, we also estimated mixed-effects regressions using the full dataset. These results are broadly consistent with those presented in the paper. Figure SI-5 shows robustness for interdisciplinarity, Figure SI-6 for the fraction of female authors cited in the readings, Figures SI-7, SI-8, SI-9 show full-model results for the age, conventionality, and the atypicality of readings.

While we report differences in percentile rank per year to address skewness in the outcome variables, we also explored alternative specificationss. First, we log-transformed our dependent variables, including the age, unconononventionality and atypicalty of readings, to explore potential non-linear relationships, particularly relevant for disciplines with old readings (e.g., history) or based on citations. Second, we employed a quasi-Poisson mixed-effect model instead of the reported linear mixed-effect regression to better account for non-linearities in the count of female authors (Figure SI-6, panel B). These changes yield similar results.

Finally, we further explored differences in team formation that distinguish between male-led and female-led courses, using the gender of the first listed instructor as a proxy for seniority. Overall, team formation trends appear robust to these additional analyses (Figure SI-10).

Figure SI-1: Women-men ratio of instructors in OpenSyllabus (OS) vs academic staff in tertiary education (ISCED 5-8) per country and year. Pearson correlation between OS and Eurostat series shown in each panel. Source: Eurostat (educ_uoe_perd02).

Figure SI-2: Women-men ratio of instructors in OpenSyllabus (OS) vs PhD graduates in the US by academic field per year. Pearson correlation between OS and representative series shown in each panel. Source: NCES (Survey of Earned Doctorates).

Figure SI-3: Pre-/Post-Covid Courses. Number of courses per CIP field (gray) in thirty-three European countries before and after Covid-19. Data from Open Syllabus (2017-2022). Smooth trend curves show the average pattern per broad field definition (ISCED-F). Most fields exhibit a significant drop in courses during the pandemic, especially Health and Welfare, Arts and Humanities, and Social Sciences and Journalism.

Figure SI-4: Heterogeneity within US courses. Estimates and 95% confidence intervals for differences in (1) interdisciplinarity (2) readings' conventionality (3) age of readings (4) female-authored ratio and (5) readings' atypicality. Estimates are from separate mixed-effects regressions for courses from the US vs the full sample, in each academic year, controlling for country, field, institution, course level, probability that the document is a syllabus, and number of readings, with weights proportional to the square root of the number of readings. Smoothed curves show local estimates averaged across years, weighted by the precision (standard errors) of the estimates. The comparison reveals no noticeable differences.

Figure SI-5: Robustness analysis for interdisciplinarity. Estimates and 95% confidence intervals from a multiple linear regression on the full sample. Dependent variable = percentile rank per year of interdisciplinarity score. Controls include the country, year, the probability of the document being a proper syllabus, field of study, institution, course levels, and (logarithm of) the number of matched readings.

Figure SI-6: Robustness analysis for female-authored readings. Estimates and 95% confidence intervals from (A) a multiple linear regression (B) quasi-poisson regression on the full sample. Dependent variable = fraction of female-authored readings to toal readings. Controls include the country, year, the probability of the document being a proper syllabus, field of study, institution, course levels, and (logarithm of) the number of matched readings.

Figure SI-7: Robustness analysis for age of readings. Estimates and 95% confidence intervals from a multiple linear regression on the full sample. Dependent variable = percentile rank of the age of publication of a syllabus' readings as (A) percentile rank per year (B) logarithm. Controls include the country, year, the probability of the document being a proper syllabus, field of study, institution, course levels, and (logarithm of) the number of matched readings.

Figure SI-8: Robustness analysis for conventionality of readings. Estimates and 95% confidence intervals from a multiple linear regression on the full sample. Dependent variable = median citations of a syllabus' readings as from references in previous syllabi as (A) percentile rank per year (B) logarithm. Controls include the country, year, the probability of the document being a proper syllabus, field of study, institution, course levels, and (logarithm of) the number of matched readings.

Figure SI-9: Robustness analysis for atypicality of readings. Estimates and 95% confidence intervals from a multiple linear regression on the full sample. Dependent variable = median Uzzi et al's atypicality of a syllabus' readings as precomputed by SciSciNet v2 as (A) percentile rank per year (B) logarithm. Controls include the country, year, the probability of the document being a proper syllabus, field of study, institution, course levels, and (logarithm of) the number of matched readings.

Figure SI-10: Robustness in the order of listed instructors. Comparing the gap between simulated and actual mixed-gender teams when the first listed instructor is a woman versus when the first listed instructor is a man.

Table SI-1: Number of Syllabi per Country

Country	Syllabi (thousands)	%
USA	3554.1	66.1
Great Britain	583.6	10.9
Canada	389.8	7.3
Italy	299.9	5.6
Poland	107.2	2.0
